The comparison of the effects of dual and single task-oriented balance exercises on postural control of patients with Parkinson's disease

Protocol summary

2015-05-16, 1394/02/26

Summary

The aim of this study is to compare the effect of single and dual task-oriented balance exercises on postural control of patients with Parkinson's disease. In this clinical trial study, 34 patients with idiopathic Parkinson's disease are randomly assigned to two groups of single and dual task-oriented balance exercises. The main inclusion criteria include having Parkinson's disease according to neurologist diagnosis, the disease progression level of 1 to 3 according to Hoehn and Yahr Scale, the ability to walk independently and without assistive device at least 10 meters in length and an acceptable level of cognitive function, i.e. score of more than 21 on the Mini Mental Status Examination (MMSE). In case of no cooperation during the test and exercises and not returning for testing after the interventions, subjects are excluded. Both groups receive 12 sessions of task-oriented balance exercises (3 sessions per week, 45 minutes per session). The group of single task-oriented balance exercises receives only a single balance exercises while the group of dual task-oriented balance exercises receives balance exercise in combination with cognitive exercises. Both groups are evaluated with clinical and laboratory tests in terms of functional balance and postural control before and after receiving exercises.
