Evaluation of the effect of 970-nm diode laser photobiomodulation combined with a neutral gel on pain perception during buccal infiltration anesthesia in maxillary anterior teeth

Protocol summary

Study aim

Evaluation of the effect of photobiomodulation using a 970-nm diode laser, combined with a neutral gel, on the perception of pain caused by buccal infiltration anesthesia in the maxillary anterior teeth.

Design

Phase II, randomized, single-blind, sham-controlled clinical trial with a 2x2 factorial, four parallel-arm, conducted on 128 patients. Allocation was performed using block randomization with variable block sizes (4 and 8) generated via Sealed Envelope.

Settings and conduct

This single-blind randomized trial will be conducted in a dental clinic. Patients are randomly assigned to four groups and receive standardized buccal infiltration anesthesia by one operator. Blinding is achieved using sham laser and neutral gel, making patients unaware of group allocation.

Participants/Inclusion and exclusion criteria

Inclusion criteria: Adults ≥ 18 years requiring maxillary anterior buccal infiltration anesthesia, ASA I-II, able to complete VAS and DAI. Exclusion criteria: Refusal of consent, allergy/contraindication to local anesthetics or epinephrine, uncontrolled systemic disease, or infection/inflammation/lesions at the injection site.

Intervention groups

Group 1: Active 970-nm diode laser without gel, followed by buccal infiltration anesthesia. Group 2: Neutral gel + sham laser, then anesthesia. Group 3: Neutral gel + active laser, then anesthesia. Group 4: Sham laser without gel (control), then anesthesia.

Main outcome variables

1. Pain intensity during needle insertion measured using a 0-10 Visual Analog Scale (VAS). 2. Pain intensity during anesthetic solution injection measured using a 0-10 Visual Analog Scale (VAS).

Scientific title

Evaluation of the effect of 970-nm diode laser photobiomodulation combined with a neutral gel on pain perception during buccal infiltration anesthesia in maxillary anterior teeth

Public title

Does photobiomodulation with a 970-nm diode laser and neutral gel reduce pain during local anesthetic injection in maxillary anterior teeth?

Purpose

Treatment

Inclusion/Exclusion criteria**Inclusion criteria:**

Adults aged 18 years and older. Patients requiring buccal infiltration anesthesia in the maxillary anterior region for dental treatment. American Society of Anesthesiologists (ASA) physical status I or II. Ability to understand and complete the Visual Analog Scale (VAS) and Dental Anxiety Inventory (DAI). Provision of written informed consent.

Exclusion criteria:

Lack of informed consent to participate in the study. Known allergy to local anesthetic agents or contraindication to the use of epinephrine. Uncontrolled systemic disease requiring specialized medical management. Presence of inflammation, infection, abscess, wound, or any soft tissue lesion at the injection site. Use of analgesics/NSAIDs, corticosteroids, sedatives, or anti-anxiety medications within 24 hours prior to the intervention. Alcohol or stimulant substance use within the previous 24 hours. Patients with acute dental pain, swelling, or requiring emergency dental treatment.

Sample size

Target sample size: **128**

Randomization (investigator's opinion)

Randomized

Randomization description

Participants will be randomly allocated to one of the four study groups using variable block randomization with block sizes of 4 and 8. The random allocation sequence will be generated by an independent statistician. Allocation concealment will be ensured using sequentially numbered, opaque, sealed envelopes (SNOSE).

Blinding (investigator's opinion)

Single blinded

Blinding description

Participants will be blinded to active versus sham laser allocation. Due to the nature of the intervention, operator blinding is not feasible.

Health conditions studied**1****Description of health condition studied**

Patients requiring buccal infiltration local anesthesia in the anterior maxillary region for dental procedures

ICD-10 code

R52

ICD-10 code description

Pain, unspecified

Primary outcomes**1****Description**

Pain induced by local anesthesia injection.

Timepoint

Pain upon needle penetration (immediately after needle insertion into the mucosa and before anesthetic injection) and Pain during injection (immediately after completion of anesthetic solution injection).

Method of measurement

Pain intensity will be measured using the Visual Analog Scale (VAS).

Secondary outcomes

1

Description

Dental anxiety level

Timepoint

before the intervention

Method of measurement

Dental Anxiety Inventory (DAI) questionnaire

Intervention groups

1

Description

Intervention group: Participants will receive photobiomodulation using a 970-nm diode laser (Sirolaser Blue, Sirona Dental Systems GmbH, Germany) with a power output of 1.5 W in continuous-wave mode and an 800-µm fiber tip. Laser irradiation will be applied to the injection site for approximately 10–25 seconds. Standard buccal infiltration anesthesia will then be administered immediately.

Category

Treatment - Other

2

Description

Intervention group: A neutral gel without active ingredients will be applied to the injection site for one minute and subsequently removed. Sham laser application will then be performed using the same device appearance, sounds, aiming beam, duration, and positioning as active laser treatment, but without therapeutic energy emission. Standard buccal infiltration anesthesia will then be administered.

Category

Treatment - Other

3

Description

Intervention group: A neutral gel will be applied to the injection site for one minute. Active photobiomodulation with a 970-nm diode laser will then be delivered using the same parameters described for Group 1. The gel will subsequently be removed, and standard buccal infiltration anesthesia will be administered.

Category

Treatment - Other

4

Description

Control group: Participants will receive sham laser treatment without gel application, followed by standard buccal infiltration anesthesia.
